

Dead Zones and Toxic Algae Bloom in US Waters

Shubh Mathur

In August 2014, toxic algae blooms in Lake Erie affected the water supply in Toledo, OH, leading to a ban on using tap water due to dangerously high levels of the toxin *microcystin*. Even though the public discourse in the former manufacturing hub centered on hanging tough and the virtues of self-reliance, half a million people lost their water supply for three days, and many continued to rely on bottled water for months afterwards. Lake Erie has one of the largest freshwater dead zones in the world. Its primary source of “nutrient pollution,” a bureaucratic euphemism with intriguing existential connotations, has been identified as the excess fertilizer washing into the lake through the Maumee River, which runs through heavily farmed areas of Indiana.

While the harmful impact of pesticides on the natural environment and particularly on insect life is now well known, excessive fertilizer use can be no less deadly. Toxic algae blooms and dead zones are the product of the paradoxical linking of *eutrophication* and *anoxia*. Excess fertilizer from fields and residential lawns washes into streams and rivers and eventually reaches the ocean. In all of these water bodies, it promotes the growth of algae, including toxic varieties.

The presence of large amounts of nutrients like phosphorous and nitrogen in the water leads to an excess of life on the surface, or *eutrophication*. The decomposition of the algae blooms produces bacteria that use up all the oxygen in the water, creating *anoxic* or dead zones, where no plant or animal life can flourish. Some types of algae blooms are toxic, and cause serious harm to humans and animals as well as marine life. Fish or seafood from waters affected by toxic algae blooms can be poisonous.

The Toledo crisis was not an isolated incident. In September 2015, an “unprecedented” patch of toxic algae covered a 500-mile stretch of the Ohio River, from West Virginia to Louisville, Kentucky. There are over 400 dead zones now in existence, mainly in coastal waters and inland lakes, concentrated in the Gulf of Mexico, the northwest US pacific coast, Western Europe, and parts of Southeast Asia.

Not all dead zones are due to human activity, but their increasing numbers and extent, recorded by oceanographers since the 1970s, are. Fertilizer runoff from agriculture and lawns is the biggest contributor to *eutrophication*, followed by discharge from wastewater treatment and industrial plants, and pollution from animal waste originating in large-scale livestock farms. The use of fossil fuels releases nitrogen oxides into the atmosphere, whereby excess nitrogen enters the water cycle. Warming water temperatures also contribute to the growth of algae blooms.

Dead zones can and have been brought back to life, largely as a result of reductions in fertilizer runoff. This can be achieved through farming practices like creating grass buffer zones around fields, especially where they border streams and other bodies of water; planting cover crops; no-till techniques; and minimizing the use of manufactured fertilizers. All of these reduce runoff. Other solutions include the introduction of shellfish like mussels which filter water, the use of fertilizers that don't contain nitrogen and phosphorous, and limiting the use of fossil fuels.

The problem, of course, is that there is no clear political path to implementing these. A case in point is the Waters of the United States rule issued by the EPA in March 2015, to clarify which waters are protected by the Clean Water Act of 1972. This rule protects streams and waterways that impact the health of waters downstream. This was a first step in limiting "non-point" sources of water pollution such as fertilizer runoff.

Opposition to the rule united a large number of groups including the Chamber of Commerce, the National Association of Manufacturers, the American Farm Bureau Federation, Dairy Farmers of America, as well as pesticide manufacturers, food and beverage manufacturers, energy and mining companies, state and local governments, water utilities, the timber industry, railroads, real estate developers and golf course operators. In October 2015, a federal appeals court in Cincinnati blocked the application of the rule nationwide.

Two types of arguments are offered against extending the 1972 Clean Waters Act. First, that the extension is an encroachment by the federal government on states' and individual owners' rights. This was the basis for the stay ordered by the federal appeals court. And secondly, that implementing any reductions in nutrient pollution would increase the cost of doing business and raise food prices. This dominant narrative views the problem in terms of trade-offs, such as cheaper food versus clean water. Environmentalists might point out that not all costs can be monetized, and long lasting damage to the environment may in itself be an unacceptable cost. New forms of advocacy and developing jurisprudence, based on notions of the Rights of Nature, may define large-scale pollution as the crime of ecocide.

The Toledo water crisis prompted Ohio to pass a new law in 2015, which governs the amount and manner of fertilizer use on farms. While this is a step forward, it cannot address the sources of pollution upriver in other states.
